AIML Phase 3 Report · Intelligence: Resume Ranking, Fairness, Attrition v2, Explanations & Pay Bands

Jaisurya Marisamy | AIML track | Phase 3 | All companies and datasets in the programme (Aura Workforce, Growmar, Zenith Nova) are fictional.

1. Student and Project Details

Name	Jaisurya Marisamy	Employee ID	GM00134
Track / Phase	AIML / Phase 3	Git tag	phase-3
Project	Intelligence: resume ranking, fairness audit, attrition v2, risk explanations, pay bands (Tasks 11 to 15)	Programme / company	AI/ML Engineer - Growmar
GitHub repository	https://github.com/jaisurya04/cortexhr (folder: phase3/)	Dataset	CortexHR_Dataset.xlsx (fictional)

2. Phase 3 Tasks and Evidence

#	Task name	Status	Evidence (paths relative to the phase3/ folder of the repository)
11	Rank resumes against job descriptions	Completed	src/cortexhr/phase3/resume/; notebooks 01 to 04; reports/task11/ranking_quality_summary.csv, misranking_analysis.csv (5 cases), top5_per_job_all_resumes.csv; docs/api_notes_resume_ranking.md
12	Audit the screener for fairness	Completed	src/cortexhr/phase3/fairness/; notebooks 05, 06; reports/task12/before_after_gap.csv, twin_pair_results.csv, ablation_masking.csv; docs/fairness/fairness_statement.md
13	Attrition model v2	Completed	src/cortexhr/phase3/attrition/; notebooks 07 to 09; HGB tuning + actual LightGBM 3-setting same-fold candidate audit; reports/task13/lightgbm_tuning_log.csv; versioned candidate + metadata
14	Explain every person's risk	Completed	src/cortexhr/phase3/explanations/; notebooks 10, 11; reports/task14/attrition_risk_2026.csv (430 rows), manual_review_10_rows.csv; Primary explanations: grouped Monte Carlo Shapley for all 430 employees; native SHAP (PermutationExplainer, shap 0.54.1) also run on all 430 employees as a separate comparison run; the 430-row HR report itself still uses the grouped Monte Carlo reasons.
15	Recommend fair pay bands	Completed	src/cortexhr/phase3/salary/; notebooks 12 to 14; reports/task15/test_metrics.csv, gender_gaps.csv, career_gap_means.csv, band_recommendations_test.csv

3. Proof That the Project Works

Component	What was done (actual)	Result / evidence
Resume ranking (T11)	TF-IDF + required and nice-to-have skill coverage + capped experience; name, e-mail, city and college-tier phrase masked; weights fixed in advance and tested with 286 weightings and leave-one-job-out.	555 human labels, 10 jobs: precision@5 0.940, hit rate@5 1.000, NDCG@5 0.923, MRR 1.000 (random: 0.166 / 0.592 / 0.266 / 0.355). Weakest job J02: only 3 relevant candidates.
Fairness audit (T12)	25 twin resumes (75 comparisons) scored before and after masking; CX-12 protected attributes validated against all 185 resumes; protected-group view regenerated. Equal group accuracy does not guarantee equal treatment of comparable individuals: a protected detail can still shift one person’s score or shortlist outcome.	Before: gap in 74 of 75 comparisons (mean 0.000126, max 0.0016) from name and e-mail words. After: mean 0.000000. NDCG@5 0.926 to 0.923.
Attrition v2 (T13)	Phase 1 pipeline and Task 3 folds; 16 HGB settings plus 3 actual LightGBM settings; LightGBM is a separate challenger. CX-15 attrition IDs and saved group counts were validated (full retraining rerun timed out).	CV ROC-AUC: baseline 0.709, HGB 0.695, v2 0.716, LightGBM 0.692 (PR-AUC 0.319). Gain is NOT proven: the 95% interval of the paired fold difference includes 0 (or is below it), so the simpler baseline is not beaten. LightGBM holdout ROC-AUC 0.696.
Risk explanations (T14)	430 employees scored; grouped Monte Carlo Shapley over 23 groups plus a native SHAP PermutationExplainer run on all 430 employees (shap 0.54.1; earlier 10-employee check used 0.50.0).	Bands {'Low': 301, 'Medium': 86, 'High': 43}; 14 of 14 format checks pass; grouped additivity 2e-16; SHAP cross-check additivity 3e-16.
Pay bands (T15)	Job-related inputs only; role average vs Ridge vs boosting on log salary; band from out-of-fold error; CX-15 protected groups validated and fairness tables regenerated.	Test MAE Rs 53,925, R2 0.983 (role average: Rs 115,094, R2 0.933); band coverage 0.80 (target 0.80). Pay ratio gap by gender (history / model with career gap / chosen model): 0.0140 / 0.0043 / 0.0025; by career gap: 0.0368 / 0.0462 / 0.0085.
Tests and traceability	8 test modules; every requirement mapped to notebook, code, output and test; all 15 notebooks cover the 38 stages and include saved outputs (not all clean-kernel rerun in this audit).	72 tests passed, 0 failed; 51 of 51 tracked requirements complete (docs/requirements_traceability.md).

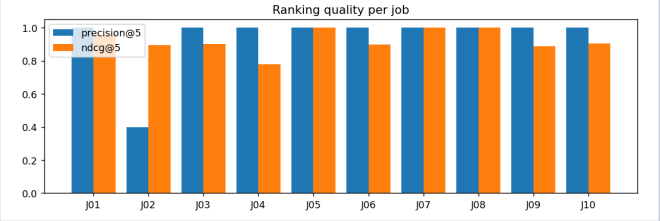

Fig. 1 Ranking quality per job (T11)

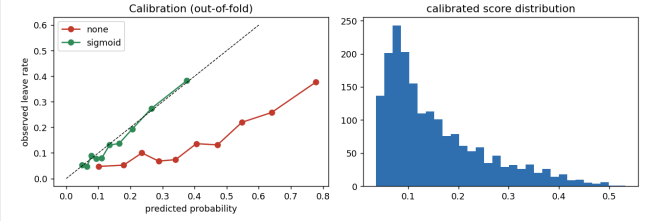

Fig. 3 Attrition calibration, before and after (T13)

Fig. 2 Twin score gap before and after masking, and ranking quality before and after (T12)

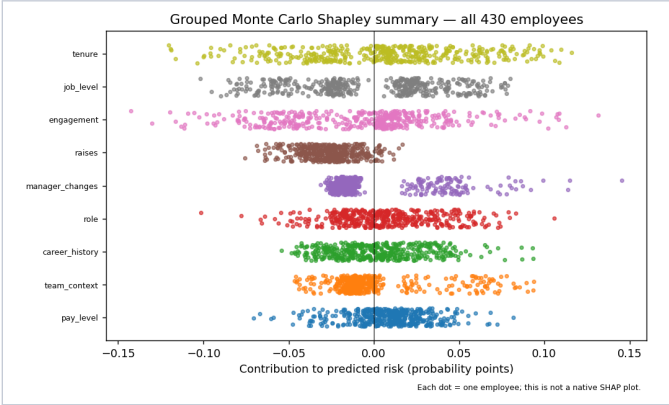

Fig. 4 Grouped Monte Carlo Shapley summary (430 employees; not native SHAP). Native SHAP was also run on all 430 employees: mean top-3 overlap 0.82, median group correlation 0.954 (T14)

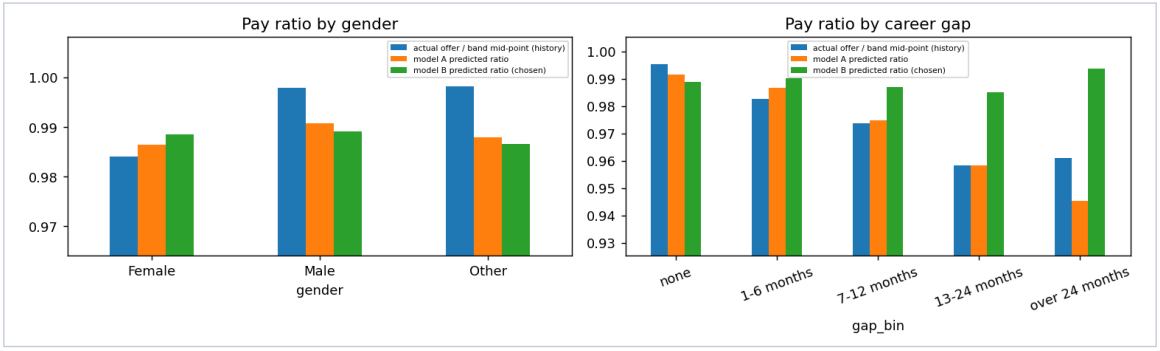

Fig. 5 Pay ratio by gender and by career gap: history, model with career gap, chosen model (T15)

```
python tests/run_all.py
test_attrition_v2            10 passed  0 failed
test_data_validation          8 passed  0 failed
test_outputs                  8 passed  0 failed
test_resume_fairness          7 passed  0 failed
test_resume_ranking          12 passed  0 failed
test_risk_scoring             7 passed  0 failed
test_salary_model            10 passed  0 failed
test_shap_explanations       10 passed  0 failed
72 passed, 0 failed
```

Fig. 6 Test run of the Phase 3 suite (output of tests/run_all.py, also runnable with pytest).

Mini challenge: one model explained to a non-technical person (the resume ranker)

- **What it does.** For each job it reads every resume, checks which of the job's required skills are really written in it, how much of the relevant experience it shows, and how similar the wording is, and puts the best candidates first with the reasons. It never sees name, gender, age, college tier, e-mail or city.
- **Why trust it.** Against 555 human judgements it put a candidate the humans also shortlisted in the top five for 100% of jobs and got 94% of its top-five right, against 17% for a random order. Twin resumes that differ only in a name now get identical scores. Every score can be explained from four numbers.
- **Where it must not be used.** Not to reject anyone automatically; not for jobs or skills outside its vocabulary; not as a probability of success; not without a recruiter reading the resume. Ten jobs and a few hundred labels are a small basis.

4. What I Learned

Free text carries what the columns hide: excluding the name column was not enough because the name and e-mail were still in the resume text, and only a twin test showed it. A fairness check can end at exactly zero when the cause is removed, but that proves one leak is closed, not that the system is fair. A bigger model is not a better model: gradient boosting did not beat logistic regression on the same folds, and class-weighted models overstate risk until they are calibrated. An explanation must add up (the efficiency check) and be reread by a human: reading ten rows aloud changed five wording rules. For pay, the data are past offers, so a model must be told not to copy a career-gap penalty.

5. Problems Faced and Solutions

Problem	How I investigated	Solution	Result / evidence
Twin resumes scored differently although skills were identical	Diffed the twin texts and masked one element at a time (ablation)	Mask name, e-mail, city and the tier phrase before scoring; neutral hash tie-break	Gap 0.000126 to 0.000000; reports/task12/ablation_masking.csv
Gradient boosting was worse than the baseline	Same folds, paired fold differences, bootstrap interval	Tried an equal-weight blend; reported that the gain is not proven	v2 0.716 vs baseline 0.709; verdict in docs/model_cards/attrition_v2.md
Class-weighted model overstated risk (mean 0.40 vs base rate 0.15)	Calibration curves and out-of-fold Brier score	Sigmoid calibration learned inside the folds	ECE 0.252 to 0.014
Optional-library reproduction	Installed LightGBM 4.6.0 and SHAP 0.50.0 for the final optional-library audit	Ran a separate LightGBM challenger on the same folds; ran native SHAP first on 10 employees, then on all 430 (shap 0.54.1, additivity error 5.6e-16); grouped Monte Carlo Shapley remains the primary 430-employee explanation method	reports/task13/lightgbm_*.csv; reports/task14/shap_library_*_cross_check.csv; automated tests
First reasons were vague, ranked a protective factor first, hinted at age	Read 10 rows aloud	Show only the 3 factors that raised the score; hide sensitive-proxy groups; reword tenure and missing data	Notebook 11; test_risk_scoring
'Misrank' counted relevant candidates at rank 9 when 15 were relevant	Checked recall limits per job	Defined misranks by pairwise inversions against human scores	5 genuine cases in reports/task11/misranking_analysis.csv

6. Plan for Phase 4

Phase 4 forecasts the future and puts everything live.

- Build a headcount and attrition forecast and compare it with a naive baseline over time (no random split).
- Serve resume ranking, risk reports and pay bands through the Phase 2 FastAPI service, with the models loaded once and every output versioned.
- Add monitoring: score drift (PSI), shortlist rate by group, calibration on new outcomes, and a documented human override.
- Re-test fairness after every change and keep the restricted files out of the repository.

7. GitHub and Submission Checklist

☑ 15 notebooks contain saved outputs and all 38 stages; not all clean-kernel rerun in final audit.

☑ 72 tests passed (python tests/run_all.py).

☑ Restricted vault files are not in the repository folder.

☑ PDF contains a clickable GitHub link.

☐ Create the Git tag: git tag phase-3

☐ Push the tag: git push --tags

☐ Verify the GitHub repository link opens.

☐ Upload this one PDF on the programme site.
